Wealth Accounting and the Valuation of Ecosystem Services
www.wavespartnership.org

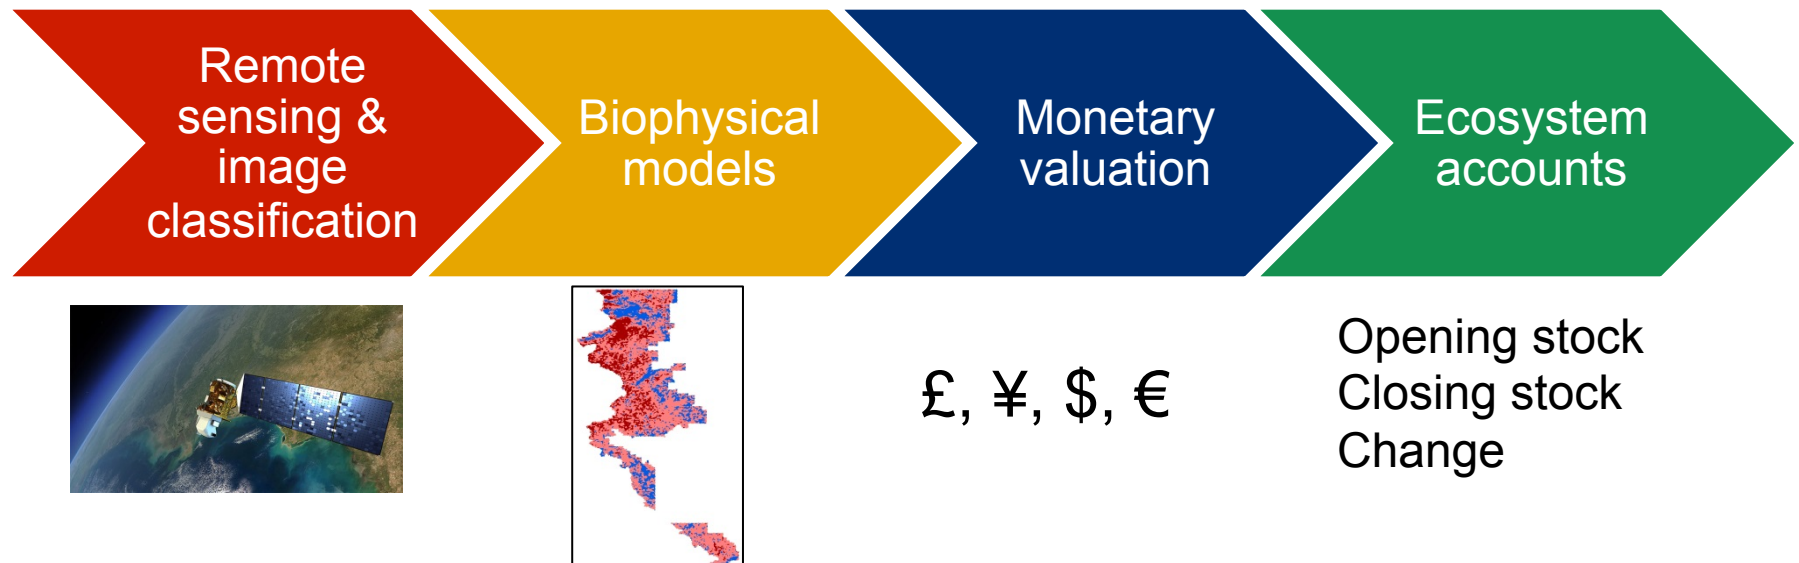

Which data source could be useful for mapping ecosystem services?

- a. A global land-cover map from an international research consortium **33%**
- b. FAO Forest Resource Assessments **24%**
- c. Population density and per capita income data from a national census bureau **5%**
- d. Soil survey data from a national mapping agency **24%**
- e. Precipitation data from a university climate research group **14%**

Why classification and data?

Who's done these steps in ecosystem services assessment and accounting?

Classification for ecosystem accounting

Classifications for accounting & ecosystem services

SEEA Central Framework:

Land, water, minerals/
energy, soil, timber,
aquatic, biological

Ecosystem service classification:

Millennium
Assessment,
CICES, FECS

**Product
classification:**
CPC, goods and
services

Industries:
ISIC, agricultural,
mining,
manufacturing, etc.

SNA Sectors:

Households, government,
financial & nonfinancial
corporations, not-for profit

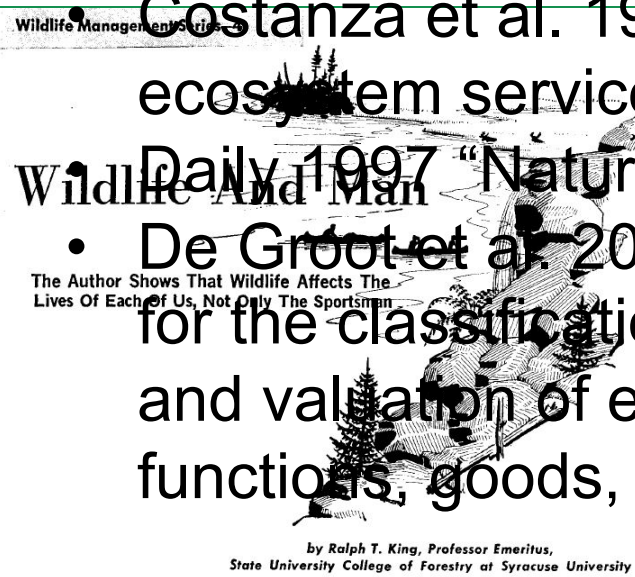

**Nonmarket
valuation methods**

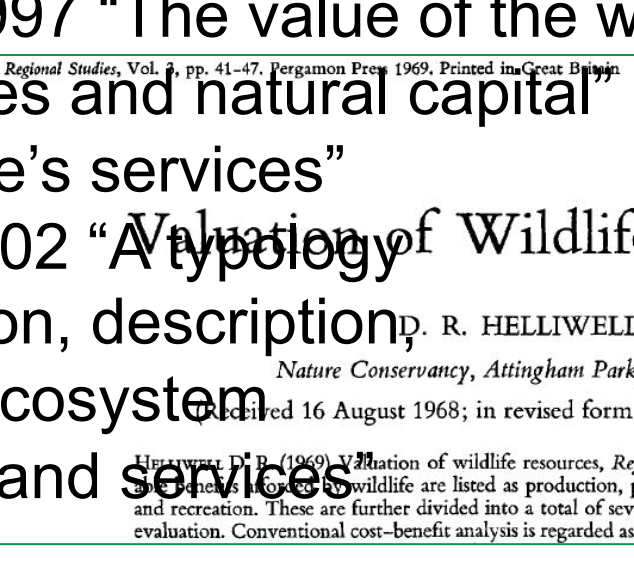

Classifying ecosystem services

1960s-2004: Major public debate for ecosystem services
 1997-2004: Major public debate for ecosystem services

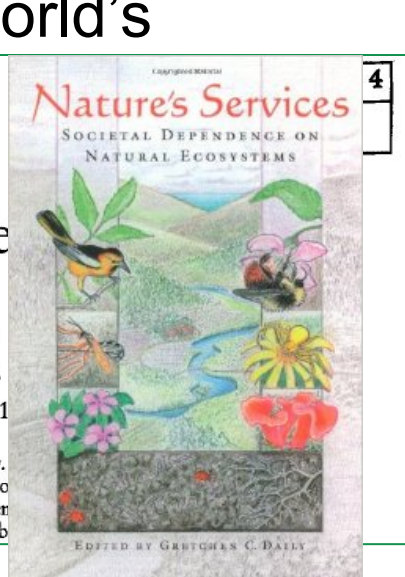

- Costanza et al. 1997 "The value of the world's ecosystem services and natural capital"
- Daily 1997 "Nature's services"
- De Groot et al. 2002 "A typology of Wildlife for the classification, description, and valuation of ecosystem functions, goods, and services"

Wildlife Management Series
 The Author Shows That Wildlife Affects The Lives Of Each Of Us, Not Only The Sportsman
 by Ralph T. King, Professor Emeritus,
 State University College of Forestry at Syracuse University

2006-
present

Common International Classification of Ecosystem Services (CICES)

Provisioning services

Nutrition

Food

Cultivated plants and domesticated animals

Wild plants and animals

Aquaculture-raised plants and animals

Water

Surface water for drinking

Groundwater for drinking

Materials

Energy

Regulating services

Provisioning:
Water, Food, etc.

Regulating:
Flood protection,
erosion control,
etc.

Cultural:
Recreation,
Existence, etc.

Data sources for ecosystem accounting

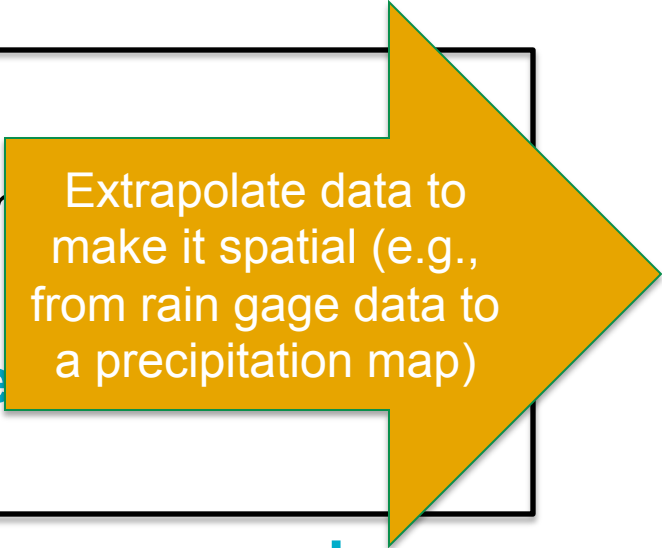

Types of data sources

Statistical data:

Agriculture, Forestry, Fisheries, Other er
Demographics, Resource use

Survey data: point-based, extrapolate

Weather data, soils, biodiversity, etc.

Extrapolate data to make it spatial (e.g., from rain gage data to a precipitation map)

Spatial data: maps generated using imagery and remote sensing

GIS: Software for spatial data

Geographic Information System (GIS) software lets a user:

Overlay and view many GIS layers

Run a wide range of analyses from simple (union, intersection, map algebra) to complex (geospatial modeling, spatial statistics)

Proprietary software: ArcGIS, others

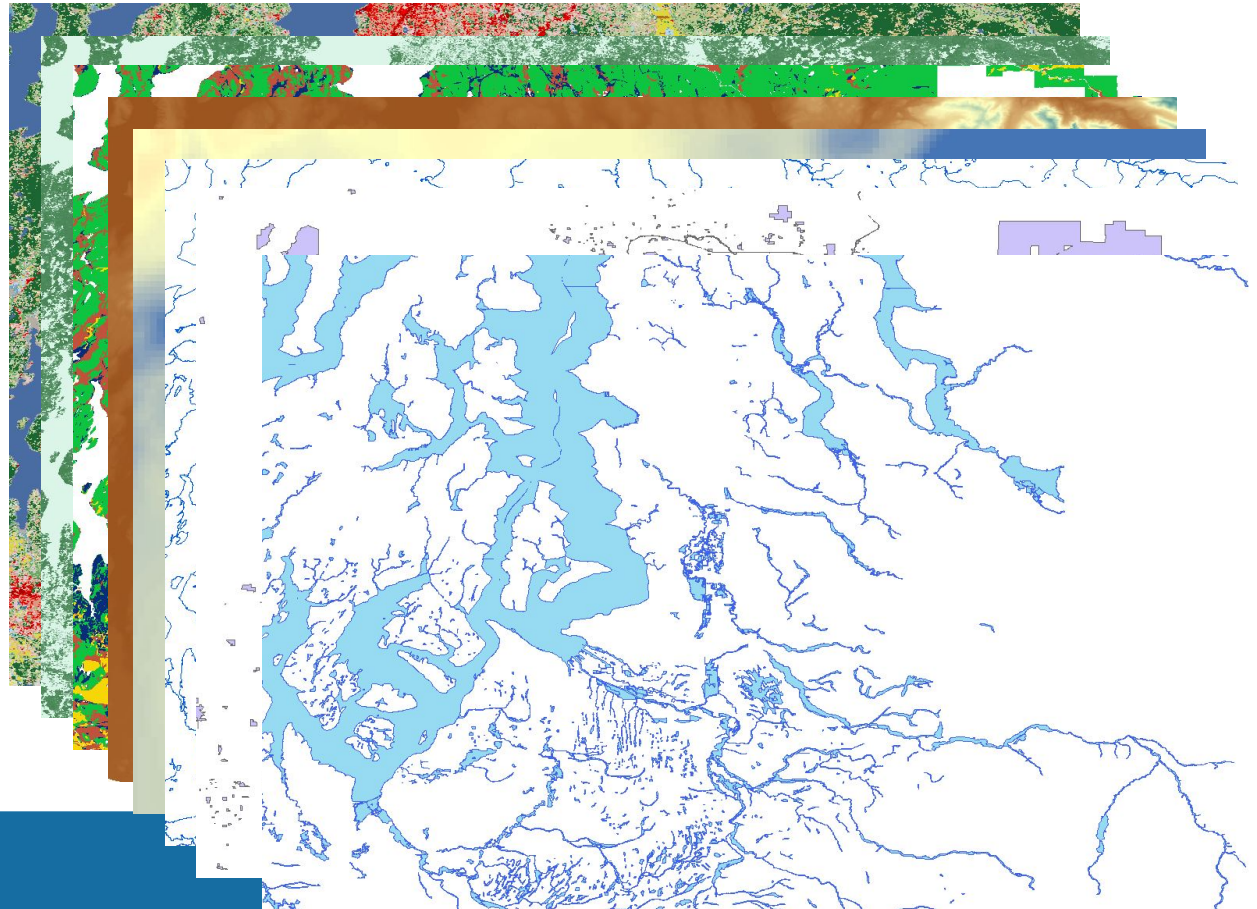

Open-source software: QGIS, GRASS, others

Spatial data themes for ecosystem services mapping

Biophysical and ecological data are often used to map ecosystem service capacity

Land cover
Vegetation
Soils
Elevation/slope
Climate
Streams
Land use
Disturbance

Spatial data themes for ecosystem services mapping

Socioeconomic data are often used to map ecosystem service beneficiaries

Population density
Infrastructure
Other demographic
data (e.g.,
vulnerability)

Where do data come from?

Satellites

Landsat 8, MODIS, European Space Agency Sentinel satellites, many others

Aerial photography (manned/unmanned aircraft)

Remote sensing: From images to datasets

Manual classification of features from images – slow, differs from observer to observer

Classification algorithms – fast, but must be well tested

All methods have some degree of error – misclassification, omission/commission error

Raster and vector data formats

Two data formats:

Raster data model
(grid cells)

Vector data model

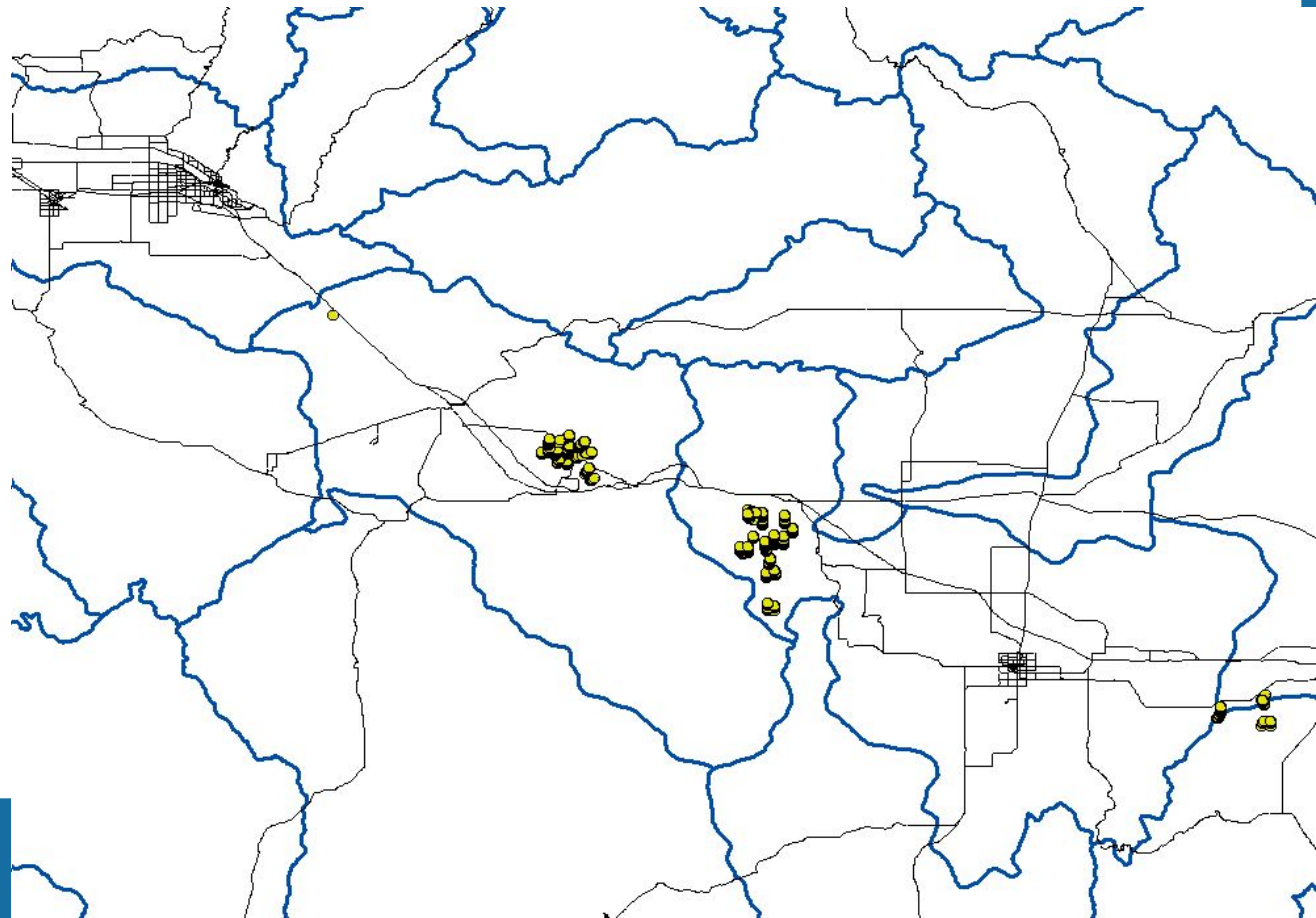

Shape (polygon), line,
or dot (point); may
carry many attributes

Can convert between the
two

Vector data formats

Vector data types: Polygon (watersheds), Line (roads), Point (wind turbines)

Information gain and loss at varying spatial resolution

U.S. National Land Cover dataset, Tucson Arizona. Native 30 m resolution (left) and resampled to 300 m resolution (right).

Information gain and loss at varying spatial resolution

Land cover	ha, 30 m dataset	ha, resampled 300 m dataset	% difference
Urban	101,203	101,538	0.4%
Forest	141,122	140,733	-0.3%
Wetland	920	909	-1.2%
Open water	315	333	5.6%
Other	672,226	671,724	-0.1%

Data management considerations

Spatial resolution (e.g., 5 m, 30 m, 1 km, 0.5 degrees²)

Greater resolution: greater disk storage needs, slower processing time

Values change with the size & shape of the units

Year of data collection (currency) – how comparable is it?

Data quality

Spatial reference system (i.e., datum, projection)

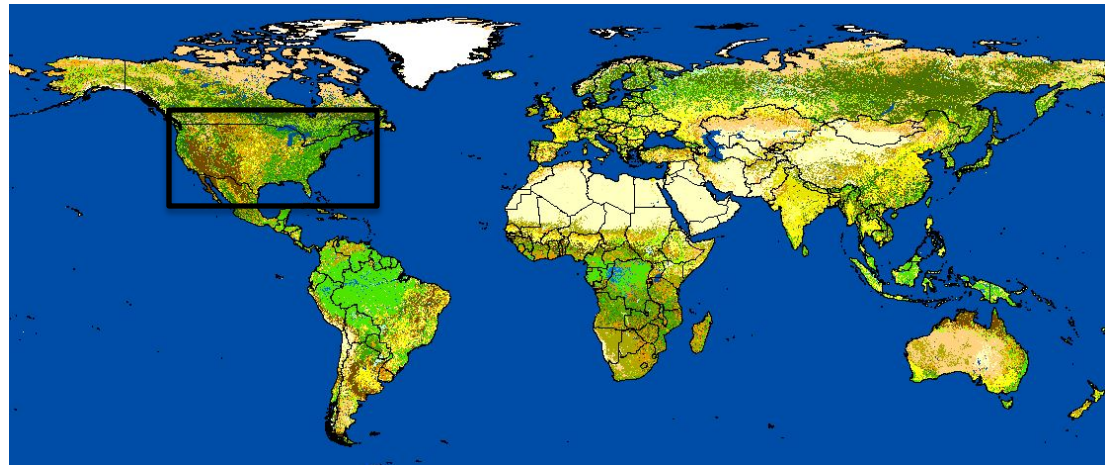

Data sources: Global & subglobal

Prepared by international organizations (U.N. agencies, international conservation organizations, academic researchers, other research consortia)

Ensure comparability between nations

May sacrifice data quality/specificity

GlobCover land cover dataset

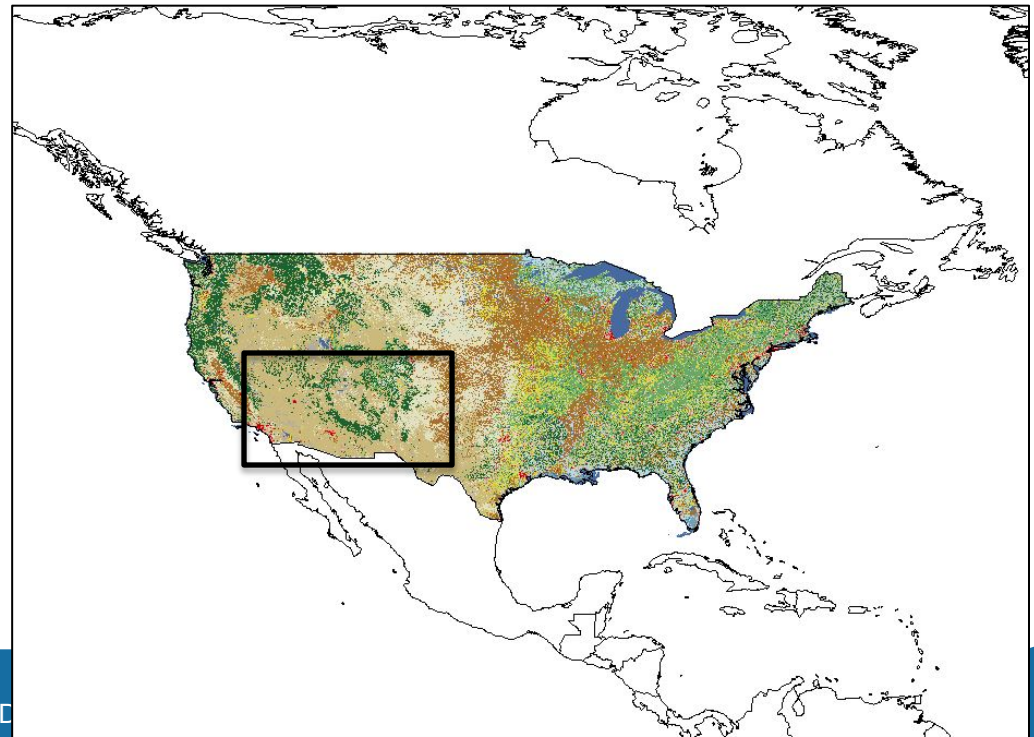

Data sources: National

Often prepared by national mapping agencies

Often highly trusted data sources for the nation

Sacrifice direct international comparability

(US) National Land Cover
Dataset

Data sources: Subnational

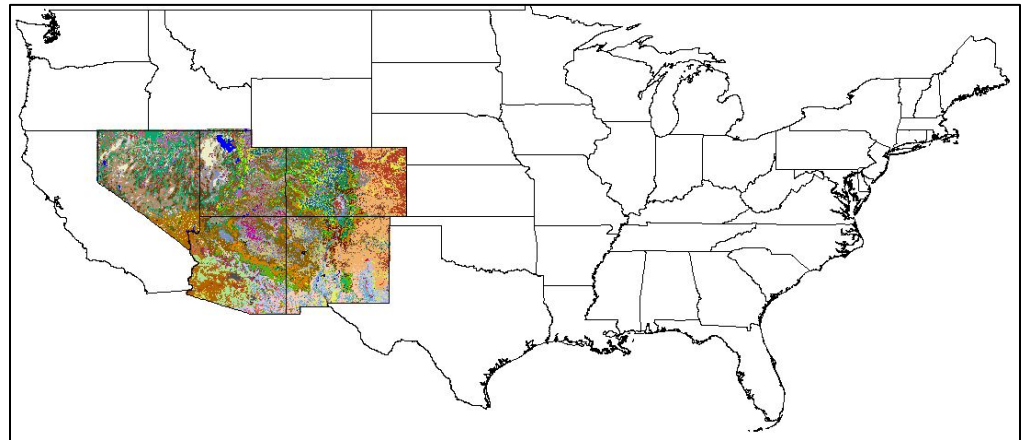

Often prepared by national mapping agencies, development aid agencies, and academics

Cover smaller spatial extents - political subjurisdictions, watersheds, biomes, etc.

May be of high quality or experimental (i.e., single year only)

Present “scaling-up” problems when not available for entire nation

Southwest (US) GAP
Analysis landcover

Key messages

Global datasets are “standard,” allow international comparability, but local data may be better for national/subnational needs

Which data are best trusted by decision makers?

High-resolution data need more storage space and processing time, but often give more accurate “answers”

GIS analysts and modelers must navigate tradeoffs between time period, resolution, accuracy

BUT: don't let the perfect be the enemy of the good

Data tradeoffs example: Denver, Colorado, USA

1. U.S. National Land Cover Dataset, 2011 (30 m)
2. GlobeLand 30, 2010 (30 m)
3. GlobCover, 2009 (300 m)

Exercise: Data for ecosystem service mapping

1. In small groups, review the CICES ecosystem services classification system and pick 2 class-level ecosystem services of interest.
2. For those services, write down 1-2 biophysical and 1-2 socioeconomic datasets needed to map and model that service.
3. For each dataset, identify a data source (i.e., national mapping agency, ministry of natural resources), and answer the following:
 1. Are corresponding global data adequate?
 2. Are national/local data of better quality than corresponding global datasets? Are they substantially better, or only somewhat better?
 3. Is the data source lacking at the national or global scale?
4. Present your conclusions to the full group for discussion.

Exercise: Data for ecosystem service mapping

Ecosystem service: Coastal flood regulation

	Biophysical		Socioeconomic	
	Dataset 1	Dataset 2	Dataset 1	Dataset 2
Dataset	Mangrove cover		Population density	
Data source	National mapping agency		Census bureau	
1. Are the corresponding global data adequate?				
2. Are the national/local data of better quality than the global data? Somewhat better or substantially better?				
3. Is the data source lacking at the national or global scale?
