2. Natural Capital Accounting for the Sustainable Development Goals: Current and potential uses and steps forward

By Arjan Ruijs,¹ Martijn van der Heide² and Jolanda van den Berg²

¹PBL Netherlands Environmental Assessment Agency
²Wageningen Economic Research, The Hague

Summary

This chapter provides a brief overview of current and potential uses of natural capital accounts (NCAs) in national policy processes for the Sustainable Development Goals (SDGs). Natural capital accounting can provide a practical framework, valuable elements, lessons, and practices that can be used to develop and implement the policies or governance arrangements needed to attain the SDGs at a country level. From the literature about the SDGs and examples discussed during the 2nd Policy Forum, we distil three general lessons about how natural capital accounting can help countries address these SDG challenges. First, we observed most attention being directed to using NCAs for the monitoring of status and trends. Natural capital accounting is seen as a useful integrated information framework used for informing the SDG policy process and ensuring integration and consistency between several of the SDG indicators. Secondly, NCAs are also helpful for policy preparation. There is a growing attention for this but, thus far, we observed limited attention for the potential role of NCAs with regard to their use in the policy-making process. This is despite the fact that NCAs may provide important input for the analytical methods in designing, implementing and reviewing evidence-based SDG policies, such as trend analysis, forecasting, footprint analysis, integrated assessment, and general equilibrium analysis. Thirdly, setting up NCAs can be helpful for building institutional coordination, and natural capital accounting and national SDG processes can benefit from one another as both use a systems-based policy framework. The SDG policy process may give a boost to setting up a process to render NCAs.

2.1 Introduction

This study was conducted in preparation of the 2nd Policy Forum on Natural Capital Accounting for Better Decision Making, on 22 and 23 November 2017, which was held in The Hague. The report provides a brief overview of how natural capital accounting is currently being used, and describes how it could contribute to attaining the Sustainable Development Goals (SDGs).¹⁰ The SDGs are the core of the “2030 Agenda for Sustainable Development,” adopted at the United Nations Sustainable Development Summit in September 2015. The 2030 Agenda is a broad sustainability action plan for all countries, focusing on the poverty–development–environment nexus and with an overarching objective of leaving no one behind. It contains 17 SDGs – see Figure 2.1 and the Appendix – consisting of 169 sub-targets, including ending

¹⁰This Forum was jointly organized by the World Bank WAVES partnership, the United Nations Statistics Division, the Dutch Ministry of Foreign Affairs and PBL Netherlands Environmental Assessment Agency.
poverty and hunger, improving health and education, combating climate change, environmental sustainability, and inclusiveness (United Nations, 2015). These goals, along with their targets and indicators, provide a detailed dashboard for the transition to sustainable development (Costanza et al., 2016).

Figure 2.1  The Sustainable Development Goals

Governments, businesses and others are working on the 2030 Agenda. Individual countries are called upon to translate global ambitions into long-term visions with clear targets and integrated policy agendas based on national circumstances (Gable et al., 2015). This process is multifaceted, with work being done to create awareness, set targets, design and implement policies, and monitor progress. So far, internationally, there is much emphasis on developing a solid framework of indicators and the underlying data needed to monitor progress of the SDGs and inform policy.

UNSD (2015) states that “the SDGs represent a step towards closer integration of policy frameworks and programmes, requiring more integrated information on the interlinkages between the economy, the environment and society.” Hence, designing and implementing the SDGs also requires an understanding of these interlinkages. This includes the impact of the economy on the long-term health of natural systems. After all, economic prosperity and human well-being are underpinned by natural capital (e.g. biodiversity, including ecosystems that provide essential services like water, food, fibres, carbon sequestration, and soil fertility).

Natural capital accounting provides such an integrated approach.\(^\text{11}\) It measures the changes in the stock of natural capital, on various scales. But perhaps more importantly, it integrates the value of ecosystem services into accounting and reporting systems at a national level (rather than maintaining a strict borderline between the economic sphere and the natural environment). As such, natural capital accounts (NCAs) provide insights into the economic

\(^{11}\) NCA is short for natural capital account, following the System of Environmental-Economic Accounting Central Framework (SEEA) and SEEA Experimental Ecosystem Accounting (SEEA EEA). NCAs include physical and monetary accounts, but also thematic and economic accounts as described in United Nations et al., (2014a,b).
importance of natural capital in wealth creation, employment, livelihoods, and poverty reduction. Through NCAs, the contribution of natural capital to economic development as well as SDGs can be made explicit (Bann, 2016) – see also the text box “Natural capital accounting and the System of Environmental-Economic Accounting.”

**Box 2.1 - Natural capital accounting and the System of Environmental-Economic Accounting**

The internationally agreed methodology for natural capital accounting is the System of Environmental-Economic Accounting (SEEA). SEEA is a central framework that contains the standard concepts, definitions, classifications, accounting rules and tables for producing internationally comparable statistics on the environment and its relationship with the economy. It guides the compilation of consistent and comparable statistics and indicators for policymaking, analysis and research (United Nations et al., 2014a).

The SEEA allows for compiling physical and monetary accounts for a range of natural resources, such as minerals, timber, and fisheries, and linking these to the System of National Accounts. It distinguishes between physical flow accounts, functional accounts, and asset accounts. The physical flow accounts record the flows of natural inputs, products and residuals within the economy and those between the environment and the economy. These include water and energy used in production, and waste flows to the environment. The physical flows are placed within the structure of a physical supply and use table, showing which products are supplied and used by the various industries and households. Functional accounts record the many transactions between industries, households and governments that concern the environment. Examples include green investments, environmental restoration, and recycling. Asset accounts in physical and monetary terms measure the natural resources available and changes in the amount available due to extraction, natural growth, discovery and other reasons. They include, for example, mineral, timber, aquatic, soil, water and land resources. In addition, the SEEA Experimental Ecosystem Accounts (SEEA EEA) present a framework for integrating biophysical data and linking changes in ecosystems to human activity (United Nations et al., 2014b). The ecosystem accounts summarise information about the extent and quality of ecosystems, their changing capacity to operate as a functional unit, and their delivery of benefits to humanity.

The World Bank-led WAVES partnership and the work programme by the United Nations Statistics Division (UNSD) promote sustainable development by mainstreaming the value of natural capital accounting in development planning and national accounting systems. WAVES and UNSD use the SEEA to produce NCAs in countries as an important tool to inform economic decision making on natural resources. Both organizations work to build capacity in individual countries to implement the SEEA and to demonstrate its benefits to policymakers. Next to this, UNSD in conjunction with the UNEP TEEB office, UN regional commissions, and the CBD initiated pilot testing of the SEEA EEA and ecosystem valuation in a number of countries.

See also [www.wavespartnership.org](http://www.wavespartnership.org), under Natural Capital Accounting resources, and [unstats.un.org/unsd/envaccounting/eu_project/](http://unstats.un.org/unsd/envaccounting/eu_project/).
A growing number of countries are compiling NCAs to inform economic decision making on natural resources. Many countries also want to use the accounts as a basis for compiling indicators to monitor progress of sustainability policies and for assessing ex ante the possible effects of new policies related to for example the SDGs. Natural capital accounting in itself does not create mechanisms to achieve the SDGs. Yet, it can provide a framework for information, valuable elements, lessons, and practices that can be used to develop and implement the policies needed to achieve the SDGs.

For this study, we investigated the design and implementation of evidence-based SDG policies – new or existing policies linked to or embedded in the 2030 Agenda – and the report outlines their current use of NCAs. It also identifies and describes opportunities for NCAs to fill gaps in information, in current SDG policy processes. In addition, we examined the institutional hurdles that prevent the creation of an environment in which NCAs could improve national policies towards achieving SDGs. In such an environment, NCAs may help to create systems-based, integrative governance arrangements spanning multiple departments, involving public and private actors, and on various spatial scales. From these analyses, we were able to derive a number of general observations that may help other countries in evaluating their position and how to use NCAs to improve their SDGs policies.

To identify current and future use of NCAs in policies to achieve the SDGs, this report first identifies four policy challenges in relation to national SDG processes (Chapter 2.2). Subsequently, it focuses on the indicators and analytical methods that are, or could be, used to address these challenges and, in particular, on how NCAs may contribute to this difficult task (Chapters 2.3 and 2.4). Chapter 2.5 illustrates the institutional hurdles countries may experience when shaping an environment in which NCAs may help to improve policies directed towards achieving SDGs. Our methodology comprised desk research, literature reviews and policy analyses, in Chapter 5 complemented by interviews and lessons learned from the 2nd Policy Forum.

It must be noted that the processes of both the SDGs and natural capital accounting are still in their infancy. At this early stage, widespread application of NCAs as a way of providing information for SDG policies cannot be expected, neither in well-developed SDG policy processes, nor in other countries, as the development and integration of the accounts in the decision-making process will take some time to accomplish (Virto et al., 2018). This has also affected which literature could be used for this report. We consulted the scientific literature, international reports (for example, by the World Bank, United Nations and OECD), as well as websites related to SDG indicators and SDG policy analyses. The available literature from any source reporting on national SDGs or natural capital accounting processes is still limited. To stay as close as possible to the SDG policy process and the focus of the 2nd Policy Forum, as well as because of time constraints, we decided not to explore the literature on green growth or sustainable development, which may also provide insights into how NCAs could support more integrated policy-making.

We focused mostly on national SDG processes, whereas, internationally, the UNSD (2015), United Nations (2017), World Bank (2017) and OECD (2016, 2017) have put much emphasis on creating coherent international indicator databases to measure progress towards the SDGs. Furthermore, for reasons of brevity, our analysis was limited to a macroeconomic perspective. Natural capital accounting for business – here defined in its widest sense as “taking the environment into account in business decision making and reporting” – has not been included explicitly.
2.2 Challenges to achieve the Sustainable Development Goals

To achieve the Sustainable Development Goals (SDGs), countries face many challenges. We distinguish four SDG-related policy challenges for which the natural capital accounts (NCAs) provide relevant information, or for which the process of producing NCAs creates a suitable environment. Of course, more types of policy challenges can be defined, but here we restrict ourselves to those that have a direct link with NCAs. The four SDG policy challenges are:

1. What is the status and trend of the SDGs?
2. What are the interrelationships – trade-offs and synergies – between the SDGs? Not only between achieving different goals, but also between various socio-economic groups.
3. Which policies or forms of governance are available to achieve the goals? This can be a broad range of governance arrangements, such as introducing economic or regulatory instruments, creating institutions, stimulating innovation or instigating transition.
4. How to create the right institutional environment for SDGs to be achieved?

The first challenge relates to all SDGs. The second and third focus on the relationships between the SDGs and the policies and governance arrangements to exploit synergies or prevent trade-offs between SDGs – see Figure 2.2.

Broadly speaking, there are four clusters of SDGs (e.g. Waage et al., 2015; Oldekop et al., 2016; Reid et al., 2017; PBL, 2017), with one cluster of SDGs focusing on social objectives (SDGs 1, 3–5 and 10), one cluster focusing on sustainable production and consumption (SDGs 2, 6–9, 11, 12), and a third cluster addressing the management of the natural resources base (SDGs 13–15). A fourth cluster is more intersecting and contains the goals addressing governance and the institutional perspective (SDGs 16 and 17) (e.g. Waage et al., 2015; Oldekop et al., 2016; Reid et al., 2017; PBL, 2017). The fourth policy challenge relates to this fourth cluster of SDGs.

The four policy challenges may occur at various stages of the policy cycle (Vardon et al., 2017) – see Figure 2.2. Challenge (a) (about status and trends), is especially relevant when problems are identified (i) and progress is monitored (iv). The policy challenges (b) and (c) (about the trade-offs and synergies and the forms of governance) are typically related to policy response (ii), policy implementation (iii) and policy review (v). Interestingly, and as presented in the case studies and synthesis presented by Vardon et al. (2017), NCAs have been or could be used during all stages of the policy cycle. For example, NCAs can be deployed to quantitatively evaluate trends (for issue or problem identification), identify entry points for interventions, and set targets (for policy response), as well as monitor and evaluate the impact of the interventions chosen (for policy monitoring and policy review).

Challenge (d) intersects with all stages of the policy cycle. Thinking only of the policy use of the accounts would risk crucial institutional issues being overlooked. According to Termeer et al. (2017), such crucial institutional risks include rigid and fragmented (instead of systems-based) policy problem frames, lack of leadership and authority to collaborate beyond departmental and organisational boundaries, inadequate resources and skills, lack of involvement from marginalized groups and local communities, inflexible governance processes, and the absence of conditions to foster the transition towards a system of integrated SDG policy-making that addresses path dependence. Challenge (d) deals with the institutional risks so that an environment for improving policies directed at achieving SDGs can be created via NCAs production.
2.3 Natural capital accounts for developing SDG indicators

SDGs are reflected in more than 200 performance indicators. Together, they form a framework that includes indicators for reporting on an international level, plus a range of national and thematic indicators that may be compiled by individual countries, based on their available capacity and policy priorities. On a national level, indicators are mainly used for monitoring, serving as barometers to gauge national progress towards achieving the SDGs. This chapter discusses three general observations:

1. NCAs may deliver a broad range of SDG indicators, including those that go beyond the natural resource base (SDGs 6, 13, 14 and 15).

2. Most attention, so far, seems to have been paid to measuring progress towards achieving a certain target. Although there is increasing attention for the relationships between SDGs, this is more often related to measurement rather than management purposes.

3. Monitoring the progress towards achieving SDGs by using existing natural capital accounts mainly occurs top-down rather than bottom-up.
Observation 1: NCAs may provide a broad range of SDG indicators, including those that go beyond the natural resource base (SDGs 6, 13, 14 and 15).

As an information system, NCAs provide the data required to determine a broad range of indicators for several SDG targets. Table 2.1 shows that natural capital is an element in most SDGs. Bann (2016) gives examples of how NCAs could support the achievement of SDGs. For instance, for SDG 6 (clean water and sanitation) many of the indicators can be directly measured using the SEEA Water methodology. More specifically, target 6.3 (improved water quality by reducing pollution) can be assessed against a SEEA-Aligned Global Indicator related to the percentage of waste water that undergoes treatment and draws information from the water accounts, namely the physical supply and use tables (PSUT) and the water emission accounts. Similarly, a fisheries account could provide information for the conservation and sustainable use of the oceans and marine resources (SDG 14) by assessing the value of stocks over time, alternative management practices, and employment opportunities. Forest accounts can also provide information for a number of the SDGs — in particular SDG 15.2, which says that, by 2020, a country should promote the implementation of sustainable management of all types of forests, halt deforestation, restore degraded forests, and substantially increase reforestation. Another goal is SDG 15.9, which calls for ecosystem and biodiversity values to be integrated into national and local planning, development processes, poverty reduction strategies and accounts, for which ecosystem and biodiversity accounts provide essential information.

The SEEA central framework (CF) comprises three main types of accounts, with each focusing on a different aspect of the interaction between the economy and the environment: the physical flow accounts (physical supply and use tables); functional accounts for environmental transactions (e.g. environmental protection expenditure accounts); and asset accounts for natural resources in physical and monetary terms. The SEEA Experimental Ecosystem Accounts (EEA) have a number of additional types of accounts, including ecosystem extent and condition accounts. It appears that all accounts are useful for estimating some of the SDG indicators. For some SDGs, the accounts directly related to the resources (e.g. the asset accounts for water, forests and fish) are obviously suitable. However, the usefulness of other accounts extends beyond the obvious examples, such as the material flow and emission accounts (see Table 2.1).

Due to the fact that NCAs produce consistent and internationally comparable statistics, they are useful to guide the development and estimation of any relevant SDG indicators — not only those related to the management of natural resources, but also those connected to other SDG clusters (see Figure 2.2). This is reflected in the experiences in some of the countries participating in the 2nd Policy Forum, such as Rwanda, Botswana, Indonesia, Costa Rica, Brazil, the Netherlands and Sweden, who use their resource and environmental accounts for SDGs related to agriculture, energy, employment, and sustainable production and consumption.12

Source: Based on the “broad-brush” analysis of SEEA-relevant SDG indicators, submitted to the Inter-Agency and Expert Group on the SDGs on 7 September 2015 (https://unstats.un.org/unsd/envaccounting/ceea/). Note that we added the column on SDG 13, as the broad-brush analysis did not consider SDG 13 on climate action.
Despite this broad application of NCAs for SDG-indicator development, we would like to make four critical remarks. Firstly, not for all SDG indicators can progress already be assessed quantitatively, and certainly not all can be determined using NCAs. A Dutch report compiled in 2017 by Statistics Netherlands (“Measuring the SDGs: An Initial Picture for the Netherlands”) describes the baseline measurement of Dutch progress in achieving the targets set for the SDGs. This report shows that, currently, 37% of the SDG indicators can be measured using the available data, some of which are based on the Dutch environmental accounts. For many indicators, data must still be collected, while several others cannot be measured quantitatively or have no established methodology or standard (Lucas et al., 2016). Here, it is worthwhile to note that the SDG process started from the goals to be achieved, and not from the indicators that can be measured or from a common measurement framework. Furthermore, not all goals are equally relevant to all countries. Hence, not all countries translate the global goals into national targets, neither do they use all or the same indicators to monitor progress.

Secondly, NCAs provide just one source of information from which progress of the SDGs can be assessed. There are also other ways to compile data or determine SDG indicators. Despite the positive experiences with NCAs for estimating SDG indicators, knowledge of NCAs and their merits for producing indicators are unknown to the many working on the SDGs. A recent UN report about data requirements for the SDGs does not even mention NCAs as a possible source of information (SDSN and TRENDS, 2017). Raising awareness of NCAs in this community remains one of the key issues.

Thirdly, despite the fact that there is plenty of theoretical work on how NCAs can contribute to SDG-indicator development, and despite the growing number of countries working on it, in practice, users cannot always be certain about how adequately the developed indicators measure the monitored phenomena. The reason for this is that it is ambiguous whether the role of monitoring is merely aimed at describing trends in SDG indicators, or whether the monitoring is to report on accountability with regard to societal and policy developments underlying the trends observed (Lucas et al., 2016).

Fourthly, although NCAs help to create an improved evidence base on the links between biodiversity and ecosystems on the one hand, and economic and human wellbeing on the other, its use concentrates mainly on environmental SDGs, less on economic SDGs, and hardly on societal SDGs. Moreover, a causal relationship between SDG policy action and environmental performance is difficult to establish, which means that providing information for policy decision-making processes through accurate accounting is a challenging task. Natural capital brings an added dimension to our understanding of the economic role of ecosystems and biodiversity and also reveals important gaps in knowledge about how these important assets should be managed to be beneficial for implementing the SDGs.

Observation 2: Most attention, so far, seems to have been paid to measuring progress towards achieving a certain target. Although there is increasing attention to the

---

13 The SDG indicator framework distinguishes three categories of indicators, called Tiers. For Tier 1, methodologies have been established and data are produced regularly. For Tier 2, the methodologies have been established, but data are not regularly produced by countries. For Tier 3, which covers 35% of the indicators, no methodologies or standards have been established yet.

14 A major consequence of this is that it appears difficult to develop indicators that satisfy the needs of the policymakers, and, hence, are relevant and useful for policy decisions.
relationships between SDGs, this is more often related to measurement rather than management purposes.

Of the challenges mentioned in Chapter 2.2, monitoring status and progress towards achieving the SDGs receives, by far, the most attention in the literature (e.g. SDSN, 2014; UNSD, 2015; Bann, 2016; Graveland et al., 2016, 2017). Supported by the custodian agencies for the various SDGs, many countries produce national reviews and assessment reports on how they are currently performing with respect to the SDG goals and targets. Most national performance reports focus on achieving a target (a report card), and less on developing implementation strategies for achieving the SDGs (policy tools). Moreover, so far, little is documented about the experience with NCAs used in comparing critical trade-offs in ecosystem service provisioning. Perhaps more importantly, there is limited evidence about whether the four environmental SDGs can be achieved simultaneously or whether they conflict, let alone how realizing these environmental SDGs can either promote or detract from the realization of the societal or economic SDGs.

This is in contrast with the basic premise of the 2030 Agenda that “the Sustainable Development Goals and targets are integrated and indivisible” (2030 Agenda for Sustainable Development, Paragraph 55), meaning that they are interrelated and mutually dependent, and must be considered and implemented as a whole. To understand how the SDGs interact, insight into synergies and trade-offs between the SDGs is needed. There are the synergies and trade-offs that may arise between economic, environmental and social goals, as well as between “here” and “elsewhere” and between “now” and “later.” So far, this has remained underexplored in the literature. Only by comparing indicators for various regions or countries, or over a series of years, can trade-offs and synergies be shown. As NCAs are particularly useful for explicitly demonstrating the interdependence between the economy and natural capital in an integrated, coherent framework, they are capable of showing the trade-offs and synergies between the SDGs, over time and between various locations.

Internationally, there is increasing attention to the interrelationships between the SDG targets, with research on interlinkages, for example, in ICSU (2017), Zhou and Moinuddin (2017), Niestroy (2016) and Nilsson (2016a, 2016b). This material shows which SDGs are especially interrelated and reinforce or counteract one another. For example, on the basis of a social network analysis of 108 of the 169 SDG targets, Zhou and Moinuddin (2017) conclude that the targets having the strongest links with other targets are those related to the following subjects:

- Agricultural productivity (target 2.3)
- Sustainable food production (target 2.6)
- Access to safe drinking water (target 6.2)
- Access to energy (target 7.1)
- Resilient infrastructure (target 9.1)

---

15 See https://sustainabledevelopment.un.org/memberstates.
16 Whether interlinkages are reinforcing, counteracting or something in between is based on a comparison of the correlations between each pair of targets. These targets are the most influential in the sense that they play multiple central roles in terms of having wider connections with other targets by exerting and receiving influences, and place at strategic positions in connecting with other influential targets (Zhou and Moinuddin, 2017). Note that it depends on the scope of your analysis which targets are found to be central targets. For example, the CD-LINKS project focuses on the links between climate change and the SDGs (www.cd-links.org) which results in other dominating targets.
For all these analyses, data were not taken from NCAs but from global data sets, such as those from the UN Sustainable Development Solutions Network, World Bank Development Indicators, Millennium Development Goals Indicators, Global Health Observatory, and the Food and Agricultural Organization statistics.\(^{17}\)

Individual countries may conduct similar analyses to assess which targets are central for their situation, provided that sufficient data are available. For this purpose, the System of National Accounts and various types of natural capital accounts can be used to determine a part of the required indicators - if they are available for a sufficiently long series of years and for sufficient natural resources and ecosystem services. To that end, the extent and condition accounts of the SEEA EEA, and the supply and use tables of the SEEA CF, show changes in the targets over time, such as for targets related to crop production, greenhouse gas emissions, share of renewable energy, protected areas, land cover, water quality, water use intensity, and waste generation.

Measuring interlinkages provides evidence about the policy themes that should be prioritized because of their reinforcing effects on various targets, and about the themes for which attention should be paid to counteract negative effects. Costa Rica is one of the few countries actively promoting the use of NCAs to show the relationships between their national sustainability objectives.\(^{18}\) These measurements, however, only provide a starting point for learning which policy instruments or governance arrangements are useful for managing these synergies and preventing trade-offs. They do not foster change. For that, further analysis is needed, as for example has been done for the case of the Central Highlands forests in Australia. Here, NCAs helped to find hotspots where environmental protection had to be assessed against competing land uses. In the study, it was found that the contribution to the economy of industries such as tourism, water and carbon far exceed that of native timber (Keith et al., 2016). Additional policy analyses can also be performed to assess the effects of the various policy instruments available – see Chapter 2.4.

Observation 3: Monitoring the progress of SDGs by using existing natural capital accounts is mainly top-down, and less bottom-up.

So far, the bottom-up approach has dominated the formulation of the SDGs. However, the SDGs can also be seen as a top-down international agenda. Achieving the goals requires both a top-down and bottom-up process. As many problems and solutions are probably most pertinent at the regional level, effort is needed to decentralize analysis and data-driven monitoring. Of course, country-specific targets also require country-specific indicators. It is, however, essential that these indicators are developed locally by a participative process to generate more transparent governance and greater accountability. Locally conceived indicators might be the best way forward to achieve the country-specific targets (Fitchett and Atun, 2014). Such a participative and “inclusive” process, however, takes time and is not always an easy task.

SDGs are thus likely to be realized through locally driven plans that reflect the priorities and contexts of individual countries, and which are based on a bottom-up perspective from policymakers and practitioners. As the economist Jeffrey Sachs says in his Kapuscinski lecture

---

\(^{18}\) See https://www.wavespartnership.org/en/2nd-forum-natural-capital-accounting-better-policy for the Costa Rican presentation during the 2\(^{nd}\) Policy Forum.
on sustainable development, “There shouldn’t be anything top-down in the Sustainable Development Goals. They should inspire actions of individuals, businesses, NGOs, governments, local authorities, everyone.”

However, despite some regional applications focusing on, for example, land use in Kwazulu Natal or the management of the Laguna Lake basin in the Philippines, NCAs mainly support national policymakers. It is hardly used for, say, raising awareness among practitioners or private actors (except for natural capital accounting at a corporate level). So, from a bottom-up perspective, NCAs appear to provide less value added than from a top-down viewpoint. Although this observation seems to go beyond the scope of this document – with its emphasis on national governmental use of NCAs – it is important, nevertheless. It is claimed that for monitoring and attainment of SDGs, a multi-stakeholder approach is needed in which “private companies, academia, multilateral institutions and civil society supports governments with the production, cleaning, composition, dissemination and analysis of data” (SDSN & TRENDS, 2017: 4). As such, the information that NCAs reveal, namely the relationship between natural capital stocks and the flows of benefits which they generate, is not only relevant for policymakers or business decision makers. The question, therefore, is how NCAs may contribute positively to changing our own individual behaviour so that SDGs come within reach?

2.4 Natural capital accounts for analyzing integrated SDG policies

The previous chapter shows that internationally, most emphasis has gone into analyzing status and trends of the SDGs for awareness raising and monitoring purposes – the first policy challenge identified in Chapter 2 – and that there is limited attention for synergies and trade-offs, the second policy challenge. While NCAs have already been used for developing some indicators for the SDGs, potentially more indicators can be determined from the accounts. In this Chapter, we investigate in more detail the role of NCAs for assessing synergies and trade-offs between the SDGs and designing governance arrangements to achieve the SDGs – the second and third policy challenges identified.

For this, we list methods that are regularly used for economic policy analysis and that could also be used to analytically assess potential SDG policies. This list is not exhaustive but rather is limited to those analytical methods that could potentially use data from NCAs. Using this list, we investigate which methods are currently used or promoted to analyze the SDGs.

Methods to analyze the SDGs

Table 2.2 shows a (not exhaustive) list of analytical methods that are potentially available for analyzing the policy challenges identified in Chapter 2.2. These methods provide useful insights for one or more stages of the policy cycle. They are applied regularly to a broad range of policy analyses and problems, but as the SDG policy process is still in its infancy, their use for analyzing the SDGs has been limited to date. All these methods can use information that can be found in natural capital accounts. However, if accounts are not available, they can also be based on other data sources. That is, for most methods, the required data does not necessarily have to be presented in the form of an account. Only for footprint analysis, input-output analysis and general equilibrium analysis, can the accounts be almost directly incorporated in the analyses.

From the literature review, three general observations can be distilled about current policy use of NCAs for achieving the SDGs, reported below (observations 4, 5 and 6).

Observation 4: The methods currently promoted for assessing the SDGs seem to pay limited attention to the potential uses of NCAs.

Since the adoption of the SDGs, several UN organisations as well as a number of other consortia have developed models to analyze the SDGs and assess the effects of SDG policies. The common thread among this suite of models is that they all attempt to promote a more systems-based approach in the SDG process and span the boundaries of the SDG process over the various scales and multiple institutions. They can also be used to show the importance of including multiple stakeholders in the process and of adapting existing policies to better consider their system-wide effects. To illustrate this, and to add some concreteness, we briefly present three examples.

First, UN-DESA has developed a suite of tools to address interlinkages that influence trade-offs and synergies between sustainable development policies, including the SDGs. These include economic models, environmental models, integrated assessment analyses and system dynamics models that rely on social accounting matrices. Second, the UN Development Group provides an SDG Acceleration Toolkit, which provides a suite of models and system-level diagnostics for analysing interconnections among SDGs. This also contains a tool focusing on the water-energy-food nexus and a dynamic social accounting matrix approach to explore interrelationships between investment planning and economic and environmental SDGs. A third example of an integrative approach, capable of analyzing and elucidating the dynamic effects of interdependencies and that is grounded in systems thinking, is the iSDGS model from the Millennium Institute and the Stockholm Resilience Centre (Collste et al., 2017). This model also uses a social accounting matrix to simulate economic flows and to balance supply and demand. Its “environment modules” track pollution due to production processes and assess renewable and non-renewable natural resource use and environmental degradation.

All three of these modelling approaches are used for national level assessments focusing on development planning and policy questions related to the SDGs. For most of these models, the natural capital accounts can readily be incorporated in the social accounting matrices, or provide otherwise useful information for the models or approaches (e.g. through some of the physical flow or asset accounts on CO₂ emissions, water, energy or materials use). However, most of the models do not mention the potential use of these accounts. It is not that the models do not recognize this potential, but the models were developed without the accounts in the first place and so are not dependant on the accounts. The supply and use tables are especially suitable for the suite of models mentioned above, given their direct link with the System of National Accounts and the social accounting matrix that is the basis of many of the modelling approaches. Yet, as long as countries lack natural capital accounts, or focus on extent, condition or thematic accounts instead of supply and use tables, other sources of

21 A social accounting matrix shows the flows of economic transactions between industries, households and governments. The matrix can be extended to also record the interactions between the economy and the environment. It is based on the system of national accounts and the natural capital accounts.

23 See www.isdgs.org.
information are needed on trends and uses of natural capital by the economic sectors, such as national or international statistics or survey data.

Observation 5: Those analyzing SDG policies seem to pay limited attention to the methods that most closely relate to the setup of NCAs.

Of the methods listed in Table 4.1, footprint analysis, input-output analysis (IO) and general equilibrium analysis (GE) are the methods most closely related to the setup of the natural capital accounts. Their data needs are consistent with the setup of the supply and use tables. However, our literature search shows that currently these methods are little used for assessing SDG policies. The main reason for this is that the SDGs were launched in 2015 and it requires time to gear the models to the sustainability issues presented. Clearly, finding a “match” between appropriate methods and the reality of SDGs in order to solve practical problems is a time-consuming process.

It is expected that more material footprint analyses will emerge in the coming years as SDGs 8 and 12, on economic growth and on responsible consumption and production, have proposed indicators based on the material footprint (e.g. Statistics Sweden, 2016). Besides that, the water, carbon, ecological, and biodiversity footprints are also useful for monitoring targets related to SDG 6 on water, SDG 13 on climate action and SDG 15 on life on land. These footprint indicators show the links between consumption or production and the environment and are helpful for prioritizing and targeting SDG policies (e.g. Hoekstra et al., 2017; Wilting et al., 2017), but their usefulness for SDG monitoring still remains to be seen. For these footprint analyses, the supply and use tables linked to the system of national accounts can be used to relate intermediate resource use and emission to end users (Edens et al., 2015).

Natural capital accounts can also be used for IO and GE models that focus on natural resources. The environmentally extended input-output table or the environmentally extended social accounting matrix used in a GE model is based on the supply and use tables from the natural capital accounts. Moreover, for some of the constraints the models need data from a range of accounts included, land cover, energy and water accounts.

The use of IO and GE models for resource-related issues is not new (e.g. Dobos and Floriska, 2007; Vaz, 2017), but the availability of NCAs makes it easier to set up models that are capable of analyzing the interrelationships between the economy and natural capital. IO analysis is seldom applied for analyzing SDGs, even though UN ESCAP (2015) promotes its use. IO analysis is easier to set up than a GE model and provides – despite its known simplifications – good first order estimates of the effects of changes in demand, technological growth or economic instruments.

A growing number of GE models are used for analyzing the environmental and economic effects of SDG-related policy choices at national or regional levels. Examples include the IEEM model (Banerjee et al., 2016) and the Inclusive Green Economy Model (IGEM) from the UNEP Partnership for Action on Green Economy (PAGE).24 The IEEM model was, for example, used to assess the interlinkages between policies related to food security, sustainable agriculture and water and sanitation in Guatemala (Banerjee et al., 2017), the relationship between

24 An example of a GE model at a global scale is the IFPRI model for analysing the water-energy-food nexus (see e.g. Willenbockel, 2016) that is used to assess the impact of climate change mitigation scenarios on energy prices, economic growth, food security and water availability.
sustainable park management and tourism in Rwanda, and for taxing emissions in Costa Rica. IGEM is an instrument for achieving the transition towards inclusive green growth and that can also contribute to achieving the SDGs. It has been used \textit{inter alia} in Peru to assess policies to achieve sustainable development, diversify the economy and create employment.\(^{25}\)

The above models rely especially on the supply and use tables of the natural capital accounts. As an alternative to this, system-dynamics models are set up. Indonesia currently uses a system-dynamics model to evaluate policy interactions, based on the stock and flow accounts. Furthermore, an example of a widely applied approach that can take advantage of the ecosystem accounts, is the InVEST model.\(^{26}\) InVEST uses land use maps and information on soil, water, erosion, etc. that can be derived from the ecosystem extent and condition accounts, to assess in a spatially explicit way the consequences of alternative land use choices and to identify areas where investments in natural capital can enhance simultaneously human development and nature conservation. An example where InVEST is used for an analysis of SDGs is the Myanmar Natural Capital Assessment that used it for multiple scale development planning and for strategic environmental assessment (Mandle et al., 2016). Moreover, the Green Growth Knowledge Platform (Narlocz et al., 2016) and the WAVES Forest Accounting Sourcebook (WAVES, 2017) mention InVEST as a tool for ecosystem services modelling and valuation that can be based on information from NCAs and used for SDG assessment. Lastly, the IEEM model also uses InVEST to include some of the biophysical feedback effects in the model.

These examples illustrate a growing number of models that directly depend on NCAs – whether they are the supply and use tables or the ecosystem extent and condition accounts – that are particularly suitable for analyzing the natural-capital-related SDGs. The disadvantage of these modelling approaches, however, is that they require strong analytical skills and that it takes time to set up and produce policy-ready results. Because neither those working at statistical agencies nor policymakers have the skills or time to successfully develop or apply the types of modelling mentioned above, this task has to be taken up by, or in conjunction with, other institutions. Many international organizations already assist with model development, but to come to actual policy use of these modelling results it is important that national research institutions or universities have the skills and resources for linking models to NCAs, in order to analyze the natural-capital-related SDGs. A growing awareness about the potential value of these modelling approaches in the SDG processes may provide triggers to further develop and spread these approaches.

**Observation 6: There is an unexploited potential of methods that directly use natural capital accounts and that are helpful in various stages of the policy cycle.**

After the modelling methods, there is an unexploited potential of other methods that could contribute to various stages of the policy cycle. The stage of problem identification and policy monitoring can be strengthened by retrospective analyses (e.g. trend analyses) and prospective analyses (e.g. trend extrapolations and forecasts). For this, time series are needed for the different indicators. As many countries, currently, do not possess a sufficiently long time series of accounts, these accounts cannot yet be used to their full potential. Over time,

\(^{25}\) See https://www.wavespartnership.org/en/2nd-forum-natural-capital-accounting-better-policy for more information about the IEEM model.

\(^{26}\) See www.greengrowthknowledge.org/sites/default/files/IGEM%20Webinar%20Final.pdf.

\(^{27}\) See www.naturalcapitalproject.org.
ongoing production of accounts will address this issue. In the meantime, if trend data are not available from natural capital accounts, other data sources may be used for trend analysis, such as the UN Global Indicators Database, the World Bank World Development Indicators, or OECD databases. These global data sets are, however, not restricted national use and they are now also being applied for international comparisons.

In addition, **scenario analysis** may provide further insight into potential synergies and trade-offs between various goals and targets (Joshi et al., 2015; Lucas et al., 2016). Scenario analysis shows the need for policy integration to reach coherence between the SDGs. For this, the natural capital accounts can be used to predict natural capital developments for given scenario assumptions, but if not available, other data sources and assumptions can be applied. To evaluate the environmental and economic consequences of a range of scenario assumptions, other analytical methods discussed later in this chapter can also be considered. Finally, for reviewing policies, **econometric analyses** can be developed to look backward at the causality of relationships between interventions and economic and natural capital developments. For such analysis, the micro-level data underlying the accounts are usually necessary. That is, the data underpinning the accounts, rather than the aggregate accounts, are needed for such analyses.

NCAs can be used for all types of analyses such as these. However, to date few countries have enough accounts available for a sufficiently long period of time to do this. As such, other ways to structure data are primarily used, mostly based on international data sets. However, due to the coherence of the SEEA framework, NCAs are more reliable and better show the extent of the linkages between sector activities and resource use and the economic, environmental and social consequences of changes therein than most other data sets. These insights are important for reaching SDG policy coherence.

### 2.5 Institutional process

This chapter focuses on the institutional hurdles that may prevent the development of an environment in which NCAs are able to improve policies directed at achieving the SDGs – policy challenge (d) identified in Chapter 2.3. To this end, we illustrate what difficulties the SDG process may face at the country level, and particularly the difficulties countries have in overcoming problems with the availability and quality of data, including data sharing mechanisms. This description is based on an internet search, interviews with resource persons in South Africa – see text box “NCAs and SDGs in South Africa” – and discussions during the 2nd Policy Forum.

**Observation 7: Natural capital accounting creates suitable institutional conditions.**

Until now, natural capital accounting has played a limited role in national policy and in the SDG processes in particular. There are several hurdles preventing an institutional environment in which NCAs can help to improve policies directed at achieving SDGs. Hurdles evident in many countries include:

- Poor availability and quality of data
- Insufficient staff with the necessary skills
- Insufficient cooperation and dialogue between statisticians, researchers and policymakers
- Lead agencies lacking the authority to enforce data sharing
- A lack of communication tailored to particular audiences, including policymakers and the wider population
That said, we found that setting up NCAs can be helpful for creating suitable institutional conditions. Some even see it as a potential game changer. Natural capital accounting brings rigour to foundational data, strengthens statistical skills, and appeals to policymakers due to their direct link with the national accounts. Moreover, we also perceive that the natural capital accounting and national SDG processes can benefit one another as both use a systems-based policy framework and require collaboration beyond departmental and organizational boundaries. Therefore, implementing NCAs should not be limited to the technical details, but should cover governance issues as well. This will help to create shared ownership and institutional cooperation, improve skills and competences in various institutions, and involve those who use the accounts so that a demand-led and iterative process is created. This helps to develop a suitable institutional environment in which NCAs can provide the evidence base needed for designing successful national SDG policies.

Box 2.2 NCAs and SDGs in South Africa

In recent years, South Africa has experienced a slowdown of its economic growth. This impedes the country’s efforts to address the huge challenges it faces: unemployment, poverty and inequality. Moreover, Reuter et al. (2016) reports that 34% of terrestrial ecosystems, 65% of marine biozones, 80% of wetlands and 82% of rivers are under degradation threat. South Africa aligned the SDGs with its National Development Plan (NDP 2030), which was affirmed in 2015. The development of the NDP 2030 involved a broad multi-stakeholder consultation process and provides a long-term strategic framework. The plan aims to eliminate poverty and reduce inequality by 2030. A range of national policies contributes to the implementation of the NDP 2030, including policies underlying a green economy planning, such as the New Growth Path.

Implementation of the NDP 2030 appears to be hampered by a number of institutional hurdles. These include:

- Limited human and budgetary capacities for the implementation of policy, plans and programs through all spheres of government, due to low economic growth
- Poor coordination and integration of program implementation, where failure to comply with governance arrangements to foster integrated implementation, monitoring and review of the NDP 2030 on the part of sectoral departments are without consequences and where the lead agency DPME lacks the opportunity to impose sanctions to enforce compliance and participation
- Shortage of skills in key sectors of the economy and a lack of a measurement culture in the public sector, which hamper monitoring of the efficacy of policy decisions and limits sustainable development
- Weak or non-existent data to support the monitoring of implementation of NDP programs. Data gaps on key NDP programs exist, or the data available is of poor or unknown quality. For example, only 62% of Tier I and Tier II SDG indicators could be reported on, and many of them only as proxy indicators or as qualitative judgements. And when quantitative data does exist, it appears that reporting on indicators is not being done as regularly as is required (see also Footnote 14)

Availability of data and information on ecosystems is quite strong, but natural capital and ecosystem accounting are still in their early days. Natural Capital Accounts include energy, fisheries and minerals. A water account is underway. Various governmental bodies play a role in natural capital accounting, see Table 2.3. South Africa also joined the global initiative to advance the SEEA Experimental Ecosystem Accounting, led by the United Nations Statistical Division.
For this, land and ecosystem accounts have been set up in KwaZulu-Natal, jointly with the South African National Biodiversity Institute (SANBI) and Statistics South Africa (Stats SA), working in partnership with national departments and the provincial conservation authority Ezemvelo KZN Wildlife. The initiative goes together with a broad stakeholder consultation, including the government, civil society, academic and private organisations, for discussing the results. Results from this are rendering input for the National Biodiversity Assessments, whereby NCAs are being used for mapping and classifying ecosystem types.

Source: Reuter et al. 2016:146.

From the interviews with resource persons in South Africa, we learned that the added value of natural capital accounting includes:

- Strengthening of and bringing rigour to the foundational data for the National Biodiversity Assessments, for example by requiring consistent time series data on land cover
- Identifying data gaps
- Integrating social, economic and environmental data and information
- Strengthening the position of ecosystem assessments into national planning processes
2.6 Conclusions and steps forward

This report provides a brief overview of current and potential uses of NCAs in national SDG policy processes. Based on a literature review, a number of interviews, and the lessons learned from the 2nd Policy Forum on Natural Capital Accounting for Better Decision Making, we investigated what has taken place in the design and implementation of evidence-based SDG policies and what role NCAs are playing or could play in these. Moreover, we examined which institutional hurdles prevent an environment in which NCAs can help to improve national policies directed at achieving SDGs. This report also provided a number of observations that are relevant for advancing the application of NCAs in the SDG processes.

From the review, we learnt that NCAs have the potential to measure several SDG indicators, and especially those related to natural capital (SDGs 6, 13, 14 and 15), but also some related to sustainable production and consumption (SDGs 2 and 12), energy (SDG 7), economic growth (SDG 8) and sustainable cities (SDG 11). The biophysical systems that underpin sustainable development are crucial for the economic and socially oriented SDGs, while human activities strongly influence the biophysical systems. So far, most attention has been paid to measuring status and trends towards achieving environmental targets. Less attention has been given to the role of NCAs in developing national implementation strategies for achieving the SDGs. This narrow focus has resulted in a more top-down process to monitor the progress of SDGs by using existing NCAs, and in less cross cutting and bottom up actions that use the accounts and indicators for developing or improving national policy processes.

We observe increasing attention on analysing interlinkages between SDGs, but this attention is focusing more on monitoring and awareness-raising than on linking or embedding existing policies in the SDG policy process or on creating new policies that focus more on the synergies between the SDGs. To date, the methods promoted for assessing the SDGs pay limited attention to the potential uses of NCAs. Due to its integrated approach, capable of showing interlinkages between the economy, the environment and society, NCAs may serve as useful input in a broad range of analytical tools. This potential seems underexploited, and especially the methods that most closely relate to the setup of NCAs – footprint analysis, input-output analysis and general equilibrium analysis. This potential is little known, not broadly advertised, but examples of use are emerging and should help to promote both NCAs and analytical methods. Given their coherent, structured and systems-based setup, NCAs can help the SDG process by promoting a systems-based approach and an institutional reform towards more integrated policy-making with multiple stakeholders and accountability bodies.

There exist several institutional hurdles that need to be addressed to increase the role of NCAs in SDG implementation, monitoring and review. These hurdles include a poor coordination and siloed implementation of activities related to natural capital accounting, scattered (or non-existent) data that are often of poor quality or not shared with others, and a lack of skills to use data to their full potential. It appears that these hurdles apply to many countries. Natural capital accounting is helpful for overcoming some of these hurdles as it brings methodological rigour to foundational data, strengthens statistical skills, and appeals to policymakers due to their direct link with the national accounts. Building NCAs that can pinpoint national progress towards achieving the SDGs and analysing the policies required to achieve the SDGs will demand investment in capacity and skills across the entire spectrum — from conceiving and collecting data, to interpreting and communicating them clearly, to making them open and accessible to all.
From this, we conclude that there is an unrealised potential for using NCAs in SDG policy processes. Despite the need for further developments, indicators and analytical methods to support the SDG process already exist and are available to countries. This requires countries to develop their natural capital accounts, so that they can be used to analyse proposed, new or existing SDG policies. However, it is unlikely that this will happen overnight.

Increasing the use of NCAs for SDG policies requires a number of developments. First, it calls for national SDG policy processes that move beyond monitoring, look at synergies and trade-offs that cross the borders between ministries, cover various spatial scales and create conditions to foster a transition to a system of integrated policy-making. Here, the development processes for the SDGs and NCAs can go hand in hand. Both processes go beyond the mandate or competences of one single institution or ministry, and depend on skilled institutions to collect data, compile accounts, undertake analysis and develop policies. Moreover, both processes require strong political support and the political will to promote evidence-based policy-making and to cross institutional boundaries. In most WAVES and UNSD partner countries, the process to implement NCAs is set up in such a way.

Second, for using NCAs as well as for analysing SDG policies, it is essential that institutions capable of applying analytical methods to produce policy-ready and easily communicable messages participate in the development of the accounts. These institutions need not analyse all SDGs from the beginning, but countries can start from those that are most relevant for them. For example, Costa Rica started with accounts for forests, water and energy to support their policies related to water use and water withdrawals (SDG 6), to monitor objectives related to renewable energy production and energy intensity (SDG 7) and monitor changes in forest assets (SDG 15). Furthermore, Botswana produced water accounts that support several policies related to poverty reduction (SDG 2), water and sanitation (SDG 6) and droughts (SDG 13). Such a prioritisation guides the accounts that have to be set up first, helps with the identification of the most relevant policy questions, steers the types of analysis that are needed and facilitates the establishment of the most appropriate governance arrangements. For this, countries do not have to reinvent the wheel over and over, but can use experiences from other countries. For this to occur, special emphasis should be put on countries communicating their results. Graphically presenting indicators is often easy, but it is more challenging to present analytical results in a way that enables policymakers to understand the relevance of the accounts and raise the right questions. This in turn enables analysts to do what is needed for policy review and design and guides statistical agencies to the compilation of the right type of accounts.

Appendix 2.1 The Sustainable Development Goals

The 2030 Agenda for Sustainable Development, adopted by all UN member states at the United Nations Sustainable Development Summit in September 2015, is a broad sustainability action plan for all countries, focusing on the poverty-development-environment nexus and with an overarching objective of leaving no one behind. It contains the following 17 Sustainable Development Goals (SDGs) – see https://sustainabledevelopment.un.org:
Goal 1. End poverty in all its forms everywhere

Goal 2. End hunger, achieve food security and improved nutrition, and promote sustainable agriculture

Goal 3. Ensure healthy lives and promote well-being for all at all ages

Goal 4. Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all

Goal 5. Achieve gender equality and empower all women and girls

Goal 6. Ensure availability and sustainable management of water and sanitation for all

Goal 7. Ensure access to affordable, reliable, sustainable and modern energy for all

Goal 8. Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all

Goal 9. Build resilient infrastructure, promote inclusive and sustainable industrialisation and foster innovation

Goal 10. Reduce inequality within and among countries

Goal 11. Make cities and human settlements inclusive, safe, resilient and sustainable

Goal 12. Ensure sustainable consumption and production patterns

Goal 13. Take urgent action to combat climate change and its impacts

Goal 14. Conserve and sustainably use the oceans, seas and marine resources for sustainable development

Goal 15. Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss

Goal 16. Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels

Goal 17. Strengthen the means of implementation and revitalise the global partnership for sustainable development
